

Diagnostic of Sagaing Region

SWOT Analysis

Strengths

- Entry Costs
- Environmental Compliance

Weaknesses

- Transparency
- Labor Recruitment

Opportunities

Sagaing Region ranks first among all states and regions in Entry Costs. However, in one township the reported difficulty of obtaining administrative documents was as high as 25%, meaning that there is still room for improvement. Improvements in weaker-performing townships can serve to further enhance Sagaing Region's overall performance.

Threats

Sagaing Region ranks last in Transparency, mainly due to its weak performance on the survey indicators. For example, none of the firms in all three surveyed townships in Sagaing Region report having access to the Union Ministries implementing documents. If not addressed, this poor performance could lead to Sagaing Region doing worse in terms of overall governance.

Diagnostic of Shan State

SWOT Analysis

Strengths

- Transparency
- Favoritism in Policy

Opportunities

Shan State scores well in Transparency, but it does relatively poorly with respect to information publicly posted and examples or relevant documents provided at township offices. Shan State has the opportunity to move to the top of states and regions with respect to Transparency, and to boost the state's overall score, if it can address issues with respect to these indicators.

Weaknesses

- Labor Recruitment
- Environmental Compliance

Threats

Shan State's poor performance on Labor Recruitment is driven by its low educational attainment. Shan does markedly worse than any other state/region on both elementary and middle school completion rates. Education is a form of human capital, and the more educated the population, in general the more competent they will be as workers and owners of firms. Poor education outcomes, if not addressed, could continue to threaten business growth in Shan State.

Diagnostic of Tanintharyi Region

SWOT Analysis

Strengths

- Land Access and Security
- Informal Payments

Weaknesses

- Post-Registration Regulation
- Infrastructure

Opportunities

Tanintharyi Region does well overall, yet it comes in last in Post-Registration Regulation. Improvements here can increase Tanintharyi Region's overall performance substantially. It lags in this subindex because it does poorly on staff helpfulness at township offices. A small adjustment in this area can garner potentially large gains to overall governance.

Threats

Tanintharyi Region tops the Favoritism in Policy subindex, but like all the other states and regions, it does extremely poorly on the number of banks and MFIs per capita. Poor access to capital is a relevant constraint for firms because they need access to money to invest further. Failure to improve along this indicator may threaten to stifle business growth in Tanintharyi Region.

Diagnostic of Yangon Region

SWOT Analysis

Strengths

- Post-Registration Regulation
- Labor Recruitment

Weaknesses

- Informal Payments
- Law and Order

Opportunities

Yangon Region does poorly in terms of crime, and its poor performance on this indicator strongly explains its poor performance on Law and Order. Improvements in this Law and Order indicator have the potential to greatly improve Yangon Region's overall index score since Law and Order is strongly correlated with business performance and satisfaction.

Threats

Yangon Region's strength in Post-Registration Regulation is driven by staff helpfulness at government offices and hard data indicators. Slippage along these indicators would lead to a substantial drop in Yangon Region's overall ranking since several other states and regions do better along survey measures of Post-Registration Regulation.

4.2. Comparisons of States and Regions

Myanmar's states and regions exhibit relatively little overall variation in economic governance compared to other countries where subnational EGIs have been conducted. Little variation means that business experience with governance is generally more homogenous and consistent than in Vietnam and Cambodia, for instance. In other words, most of Myanmar's states and regions provide adequate but mediocre economic governance, and there are few obvious superstars or laggards. Overall mediocrity may be due to the country's long history of centralized, Union-level control over policy and administration. Most of the variation in governance is within states and regions rather than across them. It is partly for this reason that this report emphasizes individual state and regional diagnostics over a direct ranking of Myanmar's states and regions. Nonetheless, a comparison of economic governance across Myanmar's states and regions does yield some interesting insights.

With respect to overall quality of economic governance, Myanmar's states and regions fall into four tiers. Although variation between states and regions is relatively muted in Myanmar, these tiers reflect distinct levels of performance as evidenced in the MBEI data. The colors in Figure 15 identify four tiers of governance, according to the rating of states and regions on the overall index. The four tiers are comprised of states and regions rated above 63, between 61 and 63, between 57 and 59, and below 57. We have selected these cut-off points because they are the locations where the tiers are relatively robust to changes in methodology. Altering the weights slightly or removing indicators changes rankings within categories but does not lead to states and regions jumping from one basket to another. This point is demonstrated in Figure 15 by the range bars depicting 95% confidence intervals around the average scores for each locality. These confidence intervals include the vari-

Most of Myanmar's states and regions provide adequate but mediocre economic governance, and there are few obvious superstars or laggards.

FIGURE 15

Margin of Error in MBEI

ance caused by sampling error and indexing construction procedures. Although the interpretation of confidence intervals is complicated, they can best be thought of as the range of MBEI scores that are possible for each state/region if we were to re-run the entire indexing methodology over again. For instance, in repeated iterations, Kayah State's score might be anywhere between 63.1 and 65.3, with the most likely score centered around 64.2.

These tiers help distinguish between real differences in governance and those that are simply artefacts of our methodological choices. When confidence intervals overlap as they do with Yangon Region and Mandalay Region, then we cannot say for certain that one has better governance than the other. In other words, this difference is not statistically significant. If we were to repeat the index procedures again, it is highly likely that their ordering could be reversed. Nevertheless, we can say for certain that Yangon Region and Mandalay Region both have significantly better governance than Ayeyarwady Region because its confidence interval is well below the confidence intervals of the other two locations and does not overlap with them. In repeated iterations of the index, it is highly unlikely that Ayeyarwady Region would surpass the other two. Knowing this fact allowed us to choose the tiers of locations that are robust to indexing methodology.

Weighting procedures play an important role in the relative performance of each state and region. In the unweighted rankings, where each subindex is treated as equally important, there is very little difference between all states and regions in the country. Different states and regions excel and underperform at different features of governance. Thus, simply adding up the subindices produces very similar scores for every state and region. There is very little variation; differences in economic governance are flat. Figure 16 illustrates this point by depicting the highest and lowest scores achieved on each subindex of the MBEI. Notice how locations such as Chin State and Kachin State appear as the highest ranked states/regions on some criteria, but also the lowest on others. Note also the number of different states/regions receiving the highest score for a particular subindex. These states/regions represent the locations with the policies that are currently the most conducive to business success and the best places to seek for potential best practices.

However, after weighting the index by the subindices that are most strongly associated with satisfaction with local government, willingness to expand business, and employment creation in the past year (see Chapter 5 and Appendix A.3), we generate the overall MBEI ranking shown in Figure 15.

Although variation between Myanmar's states and regions is relatively minor, some overall trends are observable. The two locations that measure strongest in overall economic governance are Tanintharyi Region and Kayah State, both of which border Thailand to the east. Tanintharyi Region stands out for easy access and security of land titles for SMEs, relatively low levels of informal payments at the township level, limited perception of bias toward connected companies, and high confidence of respondents in local legal institutions and law enforcement. By contrast, Kayah State ranked highly in business satisfaction with township-level road and communication infrastructure, and low influence of pollution on the agricultural, service, and food processing sectors in the state. Rakhine State and Chin State unsurprisingly have the lowest overall rankings in the index, which may result from ongoing conflicts and other challenges which command the attention of policy-makers or distract from the more mundane business-level decisions. We explore this possibility in Chapter 6.

MBEI rankings reflect the aggregate economic governance rather than the overall market or the effort of individual administrators. When comparing Myanmar's states and regions, it is important to remember the purpose of the MBEI. The MBEI does not purport to rank the overall market nor the performance of individual administrators. Markets are largely out of control of governments in the short run, and in Myanmar, economic governance is determined not strictly by the current administrator but by a history of accrued policy and administrative decisions. The MBEI is designed to measure economic governance in Myanmar as it is experienced by domestic businesses operating in the service and manufacturing sectors throughout Myanmar. In other words, these businesses are mostly SMEs and do not reflect the experience of businesses in the agriculture, fishery, forestry, or mining sectors. Rather than point to clear winners or losers, the MBEI is designed to point to areas of economic governance in which state and region governments may focus to help grow the private sector locally.

MBEI rankings reflect the aggregate economic governance rather than the overall market or effort of individual administrators.

BOX 9**Economic Governance at the Township Level**

The MBEI is also able to provide governments and businesses with a township-level picture of economic governance in Myanmar. The MBEI aggregates measurements to the state and region level in order to provide subnational governments with actionable information for improving local economic governance. However, economic governance measurements are also possible at the township level within the townships randomly sampled for the MBEI. These measurements provide a more localized and granular picture of subnational economic governance in Myanmar. Indeed, this more detailed data is particularly useful in researching the relationship between economic governance and economic growth.

The following chart illustrates the composite scores of 62 township in the MBEI nationwide sample with large enough sample sizes to generate reliable estimates. Several observations stand out. First, there is greater diversity in economic governance between Myanmar's townships than its states and regions. While legal and policy decisions may rest at the Union or state/region level, businesses nonetheless experience economic governance differently at the township level. This is likely due to differences in administration and implementation. Second, overall four distinct tiers are observable. They represent statistically significant differences between township performance in economic governance. Third, many states and regions have both good and bad performing townships. Within a given state or region, townships appear both high and low in the ranking. This relative diversity in how townships perform within a single state or region is partly responsible for the overall middling scores of most states and regions. By contrast, some states/regions—notably Chin State and Rakhine State—find their sample township overall near the bottom of the ranking. This contributes to the overall low performance of these locations.

MBEI by Township

5

Governance and Economic Growth

The MBEI provides compelling evidence of the association between economic governance and improved economic welfare in Myanmar. At the heart of the MBEI is the following question: Does improving economic governance matter? Taking steps to enhance a state or region's performance on any of the 101 MBEI indicators requires a leader's valuable time and resources as well as comprehensive planning and coordination across local actors. Understanding whether such actions are worth the effort is not a trivial exercise. A large economics and political science literature demonstrates the correlation between improvements in governance and economic performance, particularly in the areas of property rights (Acemoglu and Johnson, 2005), contract enforcement institutions (Greif, 1993; Laeven and Woodruff, 2007), and regulatory institutions (Djankov et al., 2002). But do these general relationships apply to subnational governance and welfare in Myanmar? Using the latest satellite data, the MBEI provides compelling evidence of the association between business-friendly governance practices, business responses, and welfare improvements in Myanmar. This last connection is critical since it makes clear that business-friendly policies and practices benefit not just entrepreneurs but also the broader society that relies upon private sector dynamism to provide the jobs that raise household living standards.

To research this question, we sought to observe the correlation between the Index and economic performance, using econometric analysis. Statistical regressions allow us to separate out the growth generated by initial conditions (i.e., the fundamental underlying factors that contribute to growth but are very difficult or impossible to address in the short-

term, such as location, market size, and human resources). In particular, we control for distance from Yangon (as a measure of proximity to markets), population density (as a measure of urbanization), and literacy (as a measure of human capital). Consequently, we hope to see whether governance practices explain why some areas outperform others or why some areas have similar economic outcomes despite having very different initial conditions. Actual improvements in these governance practices should lead to improvements in economic performance, even without significant changes in the physical and human infrastructure in a region.

The MBEI uses 2018 satellite data on nighttime luminosity as a proxy for economic activity. Measuring welfare poses a significant challenge. Gross Domestic Product (GDP), the standard measure of economic activity, is especially challenging to collect and analyze in developing countries, where the informal sector is large and institutional constraints can be severe. This is especially true at the subnational level. To avoid these problems, we take advantage of new technology and economic findings, which have shown that evening luminosity observed from satellites is an excellent proxy for economic activity (Chen and Nordhaus, 2011; Henderson et al., 2012; Bickenbach, 2016). We use luminosity measures from October 2018, collected immediately after the MBEI survey was completed.

In order to provide the clearest possible picture, we analyze the relationship between economic activity and economic governance at the township level. To increase our variation and precision, we disaggregate the MBEI to the township level, our primary sampling unit.

6

Variance in Economic Governance by Subgroup

Myanmar businesses experience economic governance differently based on not only their location but also characteristics of the individual business or business owner. States and regions are just one part of the puzzle. Our econometric analysis of MBEI data reveals that only 14% of the variation in final economic governance scores at the firm level is determined by variables that are measured at the state/region level. The vast majority of variation is explained by variation within individual states and regions. In other words, two businesses within the same state or region may report quite different experiences with economic governance. Township-level factors explain an additional 30% of the variation, which makes sense. As we explained in Chapter 2 above, most day-to-day business interactions occur between businesses and administrators in offices that are located within the township, such as DAO and GAD offices. The impact of past or ongoing conflicts—for example, in areas of Shan State, Kachin State, or Rakhine State—may also explain some of the variation between townships.

Businesses may experience economic governance very differently even within a single township. In fact, 56% of variation, well over half, can only be explained by factors within townships. Two potential contributing factors raised by Myanmar experts and policy advisors relate to firm characteristics: 1) variation caused by differential treatment of economic sectors and 2) gender bias toward female entrepreneurs. This chapter explains how the MBEI sought to assess the impact of these factors on economic governance in Myanmar and the key takeaways from this analysis.

6.1. Business Sector and Economic Governance

The MBEI suggests relatively little difference in how different sectors in Myanmar experience economic governance overall. This sectoral analysis takes advantage of the fact that MBEI indicators are calculated at the firm level, allowing us to aggregate to whatever level of analysis we want. In Figure 19 we create separate MBEI scores by broad sector. While we find that firms in agriculture and manufacturing believe that they are marginally better treated than firms in whole/retail trade and other services, the confidence intervals on our estimates overlap, indicating that these differences are not

statistically significant and could be simply coincidental. Further analysis of sectors further disaggregated by subsector (two-digit level) reveals a similar pattern. Economic sector and even specific industries do not matter for adjudicating overall economic governance performance.

In some cases, different sectors may experience economic governance differently with respect to specific subindices. These differences are most pronounced with respect to entry cost, post-entry regulation, land access, and competition bias. First, firms in the

FIGURE 19

MBEI by Broad Sector

Women moving sand at a construction site in Yangon

agricultural and natural resources sector face greater perceived entry costs (subindex 1) than firms in manufacturing, and both believe entry is more difficult than service sectors.¹¹ Roughly the same pattern is evident for post-entry regulation (subindex 3) and informal payments (subindex 4). Second, businesses in high-end services such as finance, insurance, and telecommunications (other services) are significantly more negative about their ability to acquire land than firms in other industries. Firms in food services are the least concerned

about land acquisition. Third and by contrast with the other indices, firms in agricultural and natural resources are less concerned about bias toward connected firms (subindex 7) and their ability to access qualified labor (subindex 9) than other sectors. Fourth, very little sectoral variation is found in access to information (subindex 6), environmental quality (subindex 8), and law and order (subindex 10); in the case of transparency and law and order, scores are generally low across all sectors. In the case of the environment, firms are generally positive.

BOX 10

Sectoral Differences Within Each MBEI Subindex

An individual business may experience certain aspects of economic governance differently depending on unique characteristics of the firm, such as its size or sector. The charts below compare how businesses in five different sectors experience each aspect of economic governance. For each MBEI subindex, average scores are provided for all survey respondents within a broad sector. Average scores are depicted with a point while bars indicate 95% confidence intervals. When confidence intervals overlap, this indicates that there are no significant differences between sectors. When confidence intervals do not overlap, these differences are meaningful and unlikely to have occurred by coincidence.

FIGURE 20

Subindices by Sector

6.2. Gender and Economic Governance

The MBEI uses regression modeling to explore the relationship between gender and economic governance. Twenty-eight percent of firms surveyed for the MBEI are owned by women. To analyze variation in treatment by gender, we use our individual-level MBEI scores in an econometric regression, where we regress the overall MBEI and each subindex on the gender of the CEO/top manager. We use only the survey results rather than the hard data and observational data, which do not vary by respondent within townships. All townships, regardless of gender, receive the same score. Figure 21 provides the results of the analysis. The bar depicts the size of the difference in perceptions between male and female entrepreneurs. A score to the right of the zero line illustrates that women evaluate governance more positively, and to the left, that they perceive men as treated better. The range bars demonstrate the 95% confidence intervals. When they overlap the zero line, the estimates

are not statistically significant. This is the case with the overall MBEI and nine out of the ten governance measures. Here, we observe no statistically significant differences between male and female business owners.

The MBEI did not find significant differences in how male and female business owners report their experience of economic governance. Among the ten subindices, only informal payments stand out with respect to gender. According to survey data, female entrepreneurs evaluate informal payments slightly more negatively than their male counterparts. However, the negative bias is only about 0.004 points, therefore it would hardly make a difference in township scores on a ten-point scale. While not substantively meaningful with respect to overall economic governance, this result does point to an important difference between male and female business owners that warrants further research.

FIGURE 21

Is Gender Associated with Governance?

Range Bars=95% CIs; Regressions control for literacy, urban population, distance from capital

7

Policy Considerations

The MBEI is designed as a starting point for identifying policy reforms to improve economic governance. In a broad-based survey that covers as much ground as the MBEI project, it is hard to provide pinpoint policy recommendations. Nothing can be improved without first being able to measure the underlying concept that needs reform. In this report, we have provided the measurement, but the next stage of research will require matching reform approaches to the problems that we have highlighted. Each of the 101 indicators used in the MBEI could be improved by multiple, different policy interventions. Future research is necessary to study Myanmar's high-performing states and regions, identify best practices using the 2019 MBEI as a baseline, evaluate governance interventions, and provide precise reform advice.

Improving local economic governance in Myanmar requires improved policy and coordination between Union and state/region governments as well as improved administration down to the township level. Law and policy relevant to Myanmar businesses is no longer strictly the jurisdiction of the Union government. Myanmar's system of dual accountability, in which departments answer to both Union and state/region ministers, means that policy improvements in economic governance increasingly must be achieved through coordination between Myanmar's two levels of government. Improving township-level administration is also key to improving local economic governance in Myanmar insofar as law and policy is implemented through government departments at the township level. The quality of local economic governance in Myanmar depends on the quality and efficiency of administration across the numerous township-level departments that interface directly with Myanmar businesses.

Several highlights from the MBEI point to key policy considerations that should be prioritized when thinking about future economic governance reforms. Efforts made to address these concerns would be the first steps at improving economic governance throughout the country. According to our research, these goals would be the least difficult to achieve (reducing informal payments and favoritism are more challenging tasks) and perhaps offer large payoffs in terms of increased business optimism and activity. For more township-specific advice, please see Chapter 4, where we provided tailored diagnostics for every state and region.

- **Improved access to information is vital for businesses.** In general, the business environment in Myanmar is not very transparent. Critical documents for business planning—such as local budgets, cadastral maps, and infrastructure maps—are often unavailable to the average business owner. Even more mundane pieces of information, such as fee schedules for licenses and other documents or instructions on land title applications, are often hard to find in many township offices. Lack of easy information generates bias in favor of those who have connections, creates opportunities for corruption, and makes strategic planning impossible. However, this governance deficit can be easily and inexpensively improved at the local level. National and local governments can put many of these documents online or post them publicly in government offices. For more complex documents and information, access-to-information policies can be created that lay out procedures for requesting

Transparency can be easily and inexpensively improved by posting relevant government documents, such as fee schedules for licenses, online or in township offices.

information from public offices and specify timelines for request fulfillment.

- **Green policies matter for the economy.** Most Myanmar SMEs are in business sectors that depend on green policies. Seventy percent of the MBEI sample are in services (mostly accommodation and food services), agriculture, or wholesale/retail. Regarding manufacturing, 30% of sample firms (44% of MOLIP firms) are in food processing. That means that 80% of the sample are in sectors where pollution is damaging to their business. Thus, quality environmental impact assessments clearly need to be prioritized at the national and local levels. As Myanmar expands and new industries enter and grow, clear zoning policies will be necessary to protect service and agricultural businesses from the more polluting manufacturing and natural-resource-exploiting industries. It will also be vital to estimate the cost of industrial expansion to existing service sector operations and to take those into account in licensing and zoning decisions.
- **Public dialogue is critical to sustainable growth.** One clear concern is how to simultaneously protect the environment while reducing regulatory procedures and inspections, which, as we have shown, are considered an obstacle to business development for many SMEs. This trade-off is a difficult one. Here, evidence has shown that consultation with the business community is critical in creating smarter regulations that protect the public interest but are acceptable to the business community. Randomized experiments have shown that public consultation leads to improved regulations, greater acceptance of those regulations by SMEs, and ultimately greater regulatory compliance (Malesky and Taussig, 2017, 2018).
- **Poor quality local labor force and difficult recruitment is costly to businesses.** Recruitment of qualified workers, particularly elite technicians and managers, is a major problem for firms in Myanmar. Over half of respondents found it difficult to recruit manual rank-and-file workers, technicians, accountants, supervisors, and managers. And finding good workers is expensive. The median firm spends 5.4% of its operating costs on labor recruitment. Taken together, these results imply that finding qualified applicants is difficult and expensive. Training and matching do not need to be resolved with direct state interventions, and encouraging private sector actors to provide vocational training and matchmaking may also help solve some of these critical employment problems.
- **Investments in education pay off.** Continued emphasis on improvements in education can help address Myanmar's labor market issues. Curriculum reform and technical and vocational training has been a priority of the current government, and rightly so. Local governments should consult with businesses about the skill set that is needed for their specific business sectors. Once these skills are understood, curriculums for vocational training can be generated at the townships and state and region levels that respond to these needs, producing the workforce that businesses need in order to expand and grow. General education is more difficult but should remain a priority of the Union government.
- **Infrastructure improvements can reduce waste and other costs.** Low quality infrastructure is leading to lost business hours and spoiled products, and quality of infrastructure appears to be a major concern for businesses in Myanmar. In particular, firms express dissatisfaction with road quality and electrical power (only 49% of firms say these features are good or very good). Firms are more positive about telephone (66% report good or very good) and Internet (54% report good or very good). Yet, even these infrastructure features have problems. The median firm reported experiencing 20 hours of lost telephone and Internet coverage and 20 hours of lost electric power in the past month, and the median firm claimed to have lost seven days of business transport activity due to flooded roads. Infrastructure creation is an expensive and long-term project, yet continued or increased expenditures by state and region governments on infrastructure will be money well spent for businesses in Myanmar.
- **Promoting improved processes can increase formalization.** Fifteen percent of businesses are fully informal, possessing no registration documentation or

Randomized experiments have shown that public consultation leads to improved regulations, greater acceptance of those regulations by SMEs, and ultimately greater regulatory compliance.

Infrastructure creation is an expensive and long-term project, yet continued or increased expenditures by state and region governments on infrastructure will be money well spent for businesses in Myanmar.

operating license for their business activities. Many of these businesses are sizable with thousands of dollars in investment and between three to ten employees. Making sure that these businesses are formalized will be necessary for implementing and enforcing regulations that protect public welfare, such as labor and consumer protection, safety and sanitary standards, and reduction in pollution. In some cases, businesses may have chosen not to receive operating licenses out of fear that the process would be time consuming and expensive, especially when informal payments are taken into account. Informing businesses that such fear is unfounded may encourage more to come out of the gray economy. In addition, efforts can be made to expedite operating license provision. Currently, it takes about seven days to receive a license, even if a firm already had one and is simply engaging in annual renewal. This recurrent cost could be eliminated with expedited licensing processes for renewals.

- **Streamlining, coordination and transparency can reduce the time costs of inspections.** Firms in Myanmar spend less time on paperwork and find officials more effective than the average Vietnamese firm. Myanmar businesses, however, are twice as likely to face regulatory inspections and are much more likely to complain that regulatory fees are not clearly posted in

local offices than similar firms in Vietnam. Of course, regulatory inspections are necessary to protect workers, consumers, and the environment, but the process should be streamlined to reduce costly waiting periods and holdups for businesses. For example, coordination between local regulatory bodies to visit firms on the same day could reduce the length of time that operations need to be shut down to accommodate them. In addition, more effort should be made to communicate to businesses exactly what their regulatory obligations are, including transparency with respect to fines and penalties for noncompliance.

- **Promote business expansion by reducing time costs of land title formalization.** For many service and manufacturing SMEs with access to a formal land title, the land titling process takes about 90 days after a firm submits all supporting documentation. This waiting period is lengthy by international standards. Given the complexity and sensitivity of land issues in Myanmar, there are likely to be a variety of reasons why titling procedures for land are so slow. Addressing these issues to reduce holdups would allow businesses to more quickly break ground and engage in the type of business expansion that generates jobs, creates revenue, and contributes to economic growth.

Office buildings in downtown Yangon

APPENDIX A

Index Methodology

The MBEI team used a three-step process to construct the Index. We refer to this process as the “three Cs.” These include 1) *collection* of data, 2) *construction* of subindices, 3) *calibration* and weighting of final index.

A.1. Collection

We utilized two general types of data to construct the MBEI subindices. The first source is perceptions data drawn from the nationally representative survey of private firms. This “soft” data was then combined with objective, or “hard,” data, which was gathered from observations at township administrative offices recorded by our field team, from statistical yearbooks, and from other administrative sources available from government ministries. The hard data was used to address perception and anchoring biases in responses. After all, many SMEs may not have an adequate understanding of other locations to rate their home state and region on a five-point scale.

A.1.1. Hard and Observational Data

Hard data, or published and other non-survey data, was used to supplement and balance MBEI survey data. This data was incorporated in the MBEI to correct for anchoring bias, control for the impact of structural endowments, and calibrate the final index scores to the relative importance of the subindices vis à vis the business environment. Hard data for the MBEI was collected through desk research and engagement with government offices during February to August 2018. Sources of hard data in the MBEI included the 2014 Myanmar Census, relevant national ministries, local offices of the GAD, and observational data of local government operations collected directly by The Asia Foundation and field research team.

A unique innovation of the MBEI compared to previous subnational indices is the addition of observational data. To collect this data, researchers visited local administrative offices, ranking various features of these offices on a number of criteria, including the public posting of vital information, the helpfulness of staff, and the availability of information upon request. The offices visited included township-level GAD, DAO, and DALMs offices.

The hard data is used in the MBEI in three important ways. The first is what is known as anchoring bias and occurs when a surveyed firm is asked to evaluate the local business environment but has little context for comparison with other regions of the country because its operations are strictly local. For example, a firm in Mon State may feel that registration procedures are fairly efficient by local standards, whereas an objective observer with knowledge of procedures across Myanmar may assess them differently. Because the hard data is not subject to perception bias, it can be used to correct for such anchoring problems in survey responses.

Figure 22 illustrates the relationship between the aggregate hard and soft indicators for each subindex in the MBEI. In most cases, the correlation is positive, and in the case of indicators regarding Entry Costs, Land Access, and Informal Payments quite strongly so. In a few subindices, such as Post-Entry regulation, the relationship is negative, which indicates that survey data in that subindex may have been influenced by perception bias in some localities.

Second, hard data is used to account for structural endowments, or aspects of the business environment that are out of the government’s control in the short run. These local endowments—such as proximity to Yangon’s large market, local market size, and readily available human capital—contribute to economic growth but are not attributable to good local economic governance. For example, literacy rates in Yangon may reflect the quality of the local labor force

that firms may draw upon, but it is unlikely to change dramatically through local government response in the short run. Similarly, proximity to the Chinese market of firms in Muse township will likely influence growth, but it is not determined by local economic governance nor is it likely to change. Consequently, the MBEI seeks to control for the impact of these factors by incorporating additional data on human capital and market proximity from non-survey sources.

Finally, the MBEI uses hard data to measure the relative importance of the various subindices (aspects of the business environment) to economic growth and calibrate the overall index score accordingly. For example, indicators commonly associated with economic growth include a large number of firms, active investment, and expansion of business operations. This data is used to generate weights for each subindex in order to construct a final MBEI score that best allows for comparisons across Myanmar's states and regions.

FIGURE 22

Correlations Between Hard and Soft Data in MBEI

A.1.2. Nationwide Business Survey

“Soft” or perceptions data for the MBEI was collected using a nationwide survey of businesses. In many ways, this survey is the signature contribution of the MBEI. The survey instrument reflected the key issues covered by the subindices and incorporated input from discussions with businesses and policy-makers. As we noted above, almost all questions focused on business interactions with township officials.

The survey instrument comprised twelve modules that were organized by topic with a final set of control questions included to assess the circumstances of the interview. The first module

collected basic information on the respondent firms, whereas the content of subsequent modules corresponds to various subindices. For example, the module related to business entry costs requested the length in days and the identification of activities that are required to register a business. By design, roughly 20% of questions on the MBEI were virtually identical to EGIs in other countries (based on Vietnam's Provincial Competitiveness Index [PCI] or the World Bank Enterprise Survey), allowing comparison across countries. In addition to straightforward inquiries of all sample firms, the MBEI instrument incorporated some additional novelties such as list experiments to shield respondents when asking sensitive questions (see Section 3.4), and a conjoint experiment (see Appendix C) to assess the impact of firm size, ownership, environmental history, industry, and other factors on the likelihood of receiving licensing and approval from local officials.

The research team subjected the MBEI survey instrument to a thorough Burmese translation. The survey was also tested and refined through focus group discussions with businesses and piloting on a subset of the eventual survey sample. Translation of the survey into Burmese began with an initial translation by the survey firm, followed by review and corrections by staff of The Asia Foundation and the DaNa Facility. The survey instrument was then circularly translated and underwent a second round of corrections. This last step involved a third party translating the Burmese-language survey into English in order to detect discrepancies in meaning and using this translation to make further corrections to the Burmese version.

In May 2018, the research team conducted focus group discussions, and in-depth interviews (IDIs) were conducted with businesses in Yangon Region and Mandalay Region, including groups of businesses owned by women and ethnic minorities. The IDIs were designed to test for sensitivity with respect to firm size, gender, and ethnicity, and led to revisions in terminology and structure of the instrument to most accurately collect data from these subgroups. In April 2018, the MBEI survey was piloted on 30 firms in four townships in Yangon Region and Mandalay Region in order to test both the content of the survey instrument and anticipated field operations. This trial led to considerable shortening of the survey instrument to accommodate the time availability of business owners and to clarify concepts. The final MBEI survey required approximately one to two hours to complete.

A.1.3. Sampling Frame

One of the first critical choices in carrying out the MBEI involved the construction of a sampling frame, or list of all businesses in Myanmar. All surveys that employ probability sampling rely upon a high-quality sampling frame covering the population of interest. However, the availability of such a list was poor in Myanmar, with most potential frames limited by insufficient coverage, significant errors, and missing contact information. As a result, the research team chose the best available list of Myanmar businesses within the timeframe of the first round of the MBEI. Various government offices in Myanmar assemble lists of registered firms, such as the Department of Labour under the Ministry of Labour, Immigration and Population (MOLIP), the SME Development Centre under the Ministry of Industry, the Directorate of Investment and Company Administration (DICA) under the Ministry of Planning and Finance, and township offices of the Development Affairs Organization (DAO). Each of these data sources come with trade-offs as to data quality, completeness, recentness, reliability, and availability. Based upon these considerations, the research team constructed a sampling frame using the 2016 MOLIP Establishment Survey data.¹²

The MOLIP data was acquired by The Asia Foundation in November 2017 and included 220,000 observations, which were used to construct a sampling frame of 60,000 firms. The frame was trimmed to 60,000 firms by restricting analysis to private, domestic operations and dropping all foreign and state-owned companies. Furthermore, to ensure that our sample had some experience interacting with government officials, the research team focused on firms with over four employees in addition to the owner. While the MOLIP data did not include a code for formality, which would have been ideal, dropping microenterprises increased the probability of identifying formal operations.

The advantages of the MOLIP data included considerably better nationwide coverage than the alternatives and its availability within the timeframe of the first MBEI round. However, there were some disadvantages. The MOLIP data had a large number of missing or incomplete addresses and appeared to need updating. Many firms listed in the dataset did not exist or had not been operation for many years. This weakness increased our noncontact and nonresponse rates and is a potential source of error in the analysis.

A.1.4. Random Sampling Procedure

Once the sample frame was selected, we then moved forward to our sampling design. In constructing the MBEI methodology, the research team faced a significant challenge. The MBEI project goals called for a sampling strategy that would yield representative results at the national, state/region, and township levels, allowing for the aggregation or disaggregation of data as necessary for the policy research. This challenge was compounded by the fact that MBEI would have large numbers of relatively inexperienced respondents. Sufficient literacy, understanding of complex governance topics, telephone numbers, and even fixed postal addresses could not be taken for granted if the project really sought to measure governance as experienced by the average business in many rural and underdeveloped localities. As a result, the MBEI survey needed to be administered in person to help explain complex topics, necessitating enormous numbers of interviewers and logistical coordination.

Because of these complexities at the design stage, the research team knew they would have to use a multistage strategy that was representative but limited the field interviewers' travels to reasonable levels. In situations where researchers are faced with a multilevel research problem that involves a small number of first-tier sampling units (i.e., townships) but need to maintain representativeness at the population level (i.e., state and region), the recommended approach of statisticians is Probability Proportion to Size (PPS) sampling. In PPS, a researcher weights each of the sampling units by the size of the population. The easiest way to think about this is as a weighted lottery, where each state and region gets a ticket for each citizen. Thus, a township with 100,000 people has ten times the probability of selection (winning the lottery) as a township with 10,000 people. A township with a population of one million has 100 times the probability of selection.

Figure 23 illustrates how the weighted lottery was carried out. Suppose the state that the researcher is working in has four townships with a total firm population size (P) of 1050. The travel and fieldwork budget only allows for two townships, but these should be randomly selected and broadly representative of the state. The researcher allocates the township "tickets" numbered 1 to 150 to the first township; the second township gets 51 to 330; the third, 331 to 530; and the fourth, 531 to 1050. Next, he/she selects a random number between 1 and $P/2 = 525$, and counts through the tickets by multiples of 525.

If the random number selected was 200, the researcher would draw tickets numbered 200 and 725, the tickets held by townships 2 and 4. Notice that the most populous township was easily selected by this procedure.

PPS therefore allows for randomness in selection, which is more likely to lead to representativeness, but has the obvious result that more populous townships are more likely to be selected. While some might consider this a bias, it is exactly the bias the research team wants. It is important to remember that the MBEI is measuring firms' experience with public administration and public service provision. It makes sense that researchers would want to know about the administration and services that affect the greatest number of businesses in a state or region. PPS also has the significant benefit of reducing field costs for research teams because interviewers do not have to be sent to many far-flung localities to do only one or two interviews. Efforts can be concentrated in the selected locations.

Within each state or region, the capital-city township was automatically selected as a "certainty unit," while several additional townships are selected randomly with PPS sampling. The certainty unit was required since many important procedures and services take place only

FIGURE 23

Demonstration of Probability Proportion to Size (PPS) Sampling

within a state or region's capital township. In analyzing the data, we use inverse probability weights to address the fact that the certainty units were not randomly sampled. The number of additional townships varied by the number of townships in the state/region and the number of total businesses in the state/region.¹³

Following this logic, the research team used the two-stage sampling procedure shown in Figure 24 below. First, townships within the 14 states and regions and Nay Pyi Taw were selected using PPS. The research design provides accurate population estimates at the township level as well as at the state and region level. Second, a stratified random sample of firms was selected from each chosen township using the size of the firm (small, medium, large) and its industry (service, manufacturing/construction, agriculture/aquaculture/natural resources), as reported in the MOLIP sample frame. Among the benefits of stratified sampling are improved population estimates and reduced sampling error, while drawbacks include the maintenance of strata in the face of a poor or incomplete sampling frame. Figure 24 illustrates the full MBEI selection strategy from state/region to township.

The appeal of this two-stage design is three-fold. On the one hand, it allows the MBEI to detect variation at the township level, where local economic governance is often implemented—as we do in our analysis of the relationship between governance and welfare (see Chapter 5). It can also help in identifying better-performing townships throughout Myanmar and highlighting the practices that make them so. On the other hand, the sampling design also allows the MBEI to report findings at the state and region level by aggregating township-level findings. This function provides a more compelling narrative to government and stakeholders, and more viable opportunities to advocate for improved local economic governance in Myanmar. A further benefit of the two-stage procedure is that it is more affordable and logistically feasible than a simple random selection. It increases the likelihood of choosing the most economically relevant units and is nonetheless random, providing the most efficient and unbiased estimates of the population.

The design's drawback is that it does not guarantee a perfect geographic distribution of the townships selected for the survey, and it may omit large subpopulations of interest (e.g., ethnic minorities, persons affected by conflict). Nonetheless, random sampling is required in order to produce unbiased estimates of the business environment at the state and region level.

A.1.5. Sample Size

The MBEI survey data consists of approximately 4,874 firms from 66 townships across all of Myanmar's 14 states and regions and Nay Pyi Taw. The data was collected during May to September, 2018, through a massive, nationwide field operation that sought to locate more than 15,000—or nearly 25% of all—private Myanmar businesses identified in the MOLIP data.

FIGURE 24

Two-Stage MBEI Sampling Strategy

The target sample size for the MBEI was calculated based on the number of townships and firms necessary to produce reliable estimates,¹⁴ which was updated as fieldwork was carried out.¹⁵ Because of the sampling procedure used, the total number of firms is driven by sample size calculations in each sample township, where small township populations require smaller samples. Initial estimates of the necessary sample size for the MBEI were strictly estimates, whereas final sample sizes reflect both common challenges in survey data collection and the actual size and nature of Myanmar's business population.

Table 4 lists the townships selected in each state and region as well as the final sample of firms included for each primary sampling unit. In addition, we provide data on the aggregate nonresponse rate in each township. This number includes all forms of nonresponse, including noncontact due to insufficient addresses or telephone-only firms, "ghost firms" that were listed in the data but were not found at their stated locations, and firms that chose not to participate in the survey. The total uncorrected nonresponse rate was 69% but varies dramatically by township. Some locations in Yangon had noncontact/nonresponse rates as high as 90%. According to the literature on strategy and policy, 70% is a reasonable response rate for surveys of busy firm managers and directors. Even so, a corrected response rate that takes into account poor addresses and ghost firms would be much higher.

Importantly, 88% of responses were filled out by the CEO or General Director, implying a high degree of accuracy and knowledge about the specific questions asked in the survey.

A.1.6. Representativeness of the Sample

Given the difficulties the research team had finding all of the firms in the MOLIP dataset and the relatively high rates of refusals in some locations, it is reasonable to ask whether the MBEI

respondents accurately reflect the underlying population in their states/regions and townships. In the section below, we present a picture of the respondents to the MBEI survey and compare them to the overall population represented by the MOLIP sampling frame. In general, MBEI firms match the underlying population extremely well. Nevertheless, MBEI respondents tend to be slightly bigger, more diversified, and more formalized than the firms listed in the dataset.

Figure 25 shows the comparison of employment size across the two datasets. In both cases, all firms simply listed their total number of employees, which we grouped into eight different categories. Most salient is that both datasets show that the average private firm in Myanmar is quite small by international standards. Over 95% of firms have less than fifty employees. Nonetheless, when comparing the micro- (<5 employees), small- (5–9 employees), and medium-sized (10–50 employees) businesses, we do notice some important differences. The MBEI respondents have a smaller share of micro-businesses (46% vs. 55%) and a larger share of medium-sized operations (26% vs. 14%). Consequently, the median firm in the MBEI survey has five employees compared to four in the MOLIP dataset. While the difference is not dramatic, we still use post-stratification weights for moderate adjustment of the data to reflect the slightly larger sample.

Table 5 explores the sampling bias by state/region, illustrating which locations differ most from the MOLIP dataset. While most states/regions have median firm employments within one or two employees of the comparison figure, the MBEI samples in Sagaing Region, Ayeyarwady Region, Yangon Region, and Chin State are three employees larger than the sample frame. We might expect that firms in these locations might be more sophisticated and successful than nonrespondents.

Figure 26 offers a similar comparison of the two datasets—this time disaggregating respondents by their broad sector of operation. Again, the MBEI sample differs slightly from the MOLIP sample frame in some important ways. In particular, the share of manufacturing firms is smaller (30% vs. 37%) and the share of total firms in services is slightly larger (66% vs. 59%) than the MOLIP dataset.

Examining manufacturing in greater detail in Figure 27, we can see that the MBEI sampling approach delivers a more diversified picture of manufacturing in the country than the MOLIP listing (44%), which is heavily weighted toward food processing, with only a tiny fraction of firms in other sectors. The MBEI sample also has a large number of firms in food processing (30%)

TABLE 5
Median Employment Size by State and Region

State/Region	MBEI	MOLIP	Difference
Shan State	4	5	-1
Kayin State	4	4	0
Tanintharyi Region	5	5	0
Bago Region	4	4	0
Magway Region	4	4	0
Rakhine State	4	4	0
Mon State	5	4	1
Nay Pyi Taw	6	5	1
Kachin State	7	5	2
Kayah State	6	4	2
Mandalay Region	6	4	2
Chin State	7	4	3
Yangon Region	8	5	3
Ayeyarwady Region	7	4	3
Sagaing Region	8	4	4

Type of Manufacturing in MBEI Sample and Population

but captures many more firms involved in machinery repair (17%) as well as wood products (13%) and basic metal production (8%).

A.2. Construction of the Subindices

A.2.1. Rescaling of Indicators

An important strength of the MBEI is that it compares economic governance against best practices already experienced in Myanmar, not against some idealized standard. For this reason, each indicator is standardized to a ten-point scale, whereby the best and worst performing recorded scores from each respondent are awarded the values of 10 and 1, respectively, and the other respondents' assessments are rescaled to fit somewhere along the scale between these two scores.

In the equation below, r represents the index for each respondent, and min and max represent the lowest and highest respective scores given in the survey. If a high value represents negative governance, we simply subtract the rescaled indicator score from 11 to reverse the scale.

$$Indicator\ Score = 9 * \left(\frac{Score_r - Score_{min}}{Score_{max} - Score_{min}} \right) + 1$$

The MBEI team calculates rescaled values, subindices, and MBEI scores for each individual firm answering the survey. Creating individual governance indices at the respondent level has the benefit of allowing us to calculate inequality in governance within every township and state or region. It also permits reaggregation, whereby we can analyze governance scores for

particular economic sectors, genders of owners, types of enterprises, or sizes of firms (see Chapter 6 above).¹⁶

A.2.2. Creating Subindices

Using the existing literature on the business environment as a guide, as well as incorporating discussion by policy-makers and economic analysts on Myanmar, indicators are grouped into the ten subindices shown above. Considerable effort was made to ensure that these subindices corresponded with previous research on the obstacles to private sector entry and growth in Myanmar (see Appendix B for a full discussion of each indicator).

Once the indicators are standardized, a weighted average of all indicators is taken to create the subindex at the respondent level. Weighted averages are employed to better incorporate hard data when available. To limit perception biases, survey data received a weighting of 60%. Hard data always received 40% of the weight in the subindices.

A.3. Calibration of the Final MBEI

A simple summation of the ten subindices yields the unweighted index with a maximum possibility of 100 points. While this method is clearly the easiest and simplest one to calculate the final MBEI, it would be inappropriate as a policy tool for the simple reason that some subindices are more important than others in explaining private sector development. Hence, it is important to reweight subindices based on their actual contributions to firm satisfaction with governance and other outcomes like business performance. To do this, the research team used multivariate regression analysis to determine how each of the subindices influences the key economic performance variables that researchers and practitioners in Myanmar have deemed the most important gauges of private sector development.

- **Average confidence in local government leaders.** Question 184 of the MBEI asked the following question of all levels of government:

The new leadership has made commitment to improve the business environment through formal laws and regulations, but also in informal speeches and communications with firms like yours. How confident are you that leaders of the following agencies will take action to implement their commitment based on your experience with previous commitments?

The question was coded on a four-point scale, with 4 representing “very confident” and 1 representing “no confidence at all.” We averaged the confidence scores for the four levels of government that most influence business performance: state and region government, GAD, DAO, and city development councils like YCDC.

- **Overall business performance in 2017**, which is taken from Question 20 of the MBEI survey, measures the net profit or losses of the business during the year. The assumption is that, when controlling for structural and market factors, economic governance should have a significant relationship with business success. Profit of firms in a one-time period is a very good predictor of the potential for more investment in subsequent periods as more firms enter the market. Competitive states and regions are more likely to create an environment in which entrepreneurialism is encouraged and rewarded by business profits, rather than by public largesse.
- **Willingness to expand**, taken from Question 21 of the MBEI survey, asks:

Which statement best characterizes your firm’s investment plans over the next 2 years? If you are considering expansion in any portion of your business, please let us know.

We then record plans to “increase the size of their operations.” In Vietnam, this measure has become an elegant indicator of optimism and confidence felt by the private business community regarding its economic prospects (Malesky et al., 2018). It is a strong leading

indicator of per capita GDP growth in the state or region.

In each case, while regressing the above economic performance variables, the research team controlled for firm-level differences in initial structural conditions of private sector development,¹⁷ specifically:

- the employment size of the business when it started operations and the sector (two-digit level) in which it competes,
- the average literacy of the state or region as a measure of human capital endowment,
- the average urbanization of the state or region (urban population/total population) as a measure of market size and initial economic development.

Regression results for the three different outcome variables are shown in Figure 28. Regression outcomes were then rounded to deliver basic classes of weights, as shown in the NE panel of Figure 28 and the final column of Table 6. Subindices that have the largest association with private sector growth—Environment (subindex 8), Labor Recruitment (subindex 9), and Law & Order (subindex 10)—receive the highest weight class of 20%. Correspondingly, those that are not strongly correlated with private sector development outcomes receive the lowest weight class of 2.5%. They include Land Access (subindex 2), Transparency (subindex 5), Infrastructure (subindex 6), and Favoritism in Policy (subindex 7). The medium weight class of 10% is reserved for average correlations across the three outcome variables or for a large substantive effect on one outcome (e.g., profitability) with minimal effects on the other two, such as Entry Costs (subindex 1), Post-Entry Regulation (subindex 3), and Informal Payments (subindex 4).

FIGURE 28

Labor Recruitment	8	1. Survey Data (60%) 2. Hard and Observational Data (40%)	20
Law & Order	11	1. Survey Data (60%) 2. Hard and Observational Data (40%)	20

APPENDIX B

Description of Indicators Used in the MBEI

B.1. Indicator Descriptions and Data for Entry Costs Subindex

A fundamental constraint on business growth and development is the level of bureaucratic impediments and the associated time and monetary costs that prolong a firm’s ability to start a business. The entry costs subindex measures the extent of these business challenges. For example, government agencies may take too long to issue permits or require an excessively large number of documents before a business can begin operations. Firms have limited resources, and the excessive burden imposed on firms by inefficient bureaucracy makes both firms and consumers worse off; consumers do not get to purchase the products they desire, and firms lose out on potential sales as they wait to begin operations.

1. Length of time to get all required registration certificates, licenses, and stamps to become a fully legal business (q41; this variable is SHARE that took more than three months)

The length of time required to obtain all relevant documents, licenses, and stamps is another helpful indicator of entry costs: the more days it takes, the higher the cost; the fewer days it takes, the lower the cost. This indicator is defined as the share of firms that took longer than three months to procure all the required documentation. We believe that firms that take more than three months to procure all the necessary documents are subject to unnecessary opportunity costs, economic losses, and uncertainty, which make the underlying costs of setting up a business prohibitively high (World Bank, 2018). This indicator may speak to the presence of red tape and inefficiency—similar to the previous indicator—but may also imply a lack of information; both the bureaucrat and the entrepreneur may not know which documents are required to formally register a business or the necessary formal steps that are required to do so (Lambert et al., 2012). One concern with this indicator is that some firms may not understand their legal responsibilities and therefore may under- or over-estimate the requirements.

2. Number of additional documents needed (q42)

The more documents needed to fully register a business, the higher the cost of business entry. The rationale for this indicator is straightforward; each additional document is costly to procure, taking up some of the entrepreneur’s time and money, while also introducing added uncertainty as to whether the entrepreneur will receive the document on time (if the document comes at all). Since each document comes with increased entry costs, the total number of documents is a useful indicator of the total entry costs to setting up a business (Ciccone and Pappaioannou, 2007). The submission process for DICA registration is delineated in the 2017 Companies Law.

3. Number of days from hire of service until receipt of company registration certificate from City Development Committee (q38_1_1)

4. Number of days from hire of service until receipt of operating license from the Township Development Affairs Organization (DAO) (q38_1_2)

5. Number of days from hire of service until receipt company registration certificate from the Directorate of Investment and Company Administration (q38_1_3)

These last three indicators show the number of days it took for the firm to apply for the relevant entry document from the municipal CDC, the township DAO, or the national-level DICA (Bissinger, 2016). We use the document that the business claims to have obtained most recently. These indicators measure entry costs to a business because the longer it takes to receive a document, the greater the opportunity cost to setting up the business (World Bank, 2018). In other words, the potential entrepreneur is spending money and time registering the business when

he/she can be using this time in more productive, income-generating ways. Another cost is the uncertainty over whether the document will ultimately be provided: the greater the uncertainty, the costlier it may be for the entrepreneur to consider starting the business in the first place (Knight, 2012; McMullen et al., 2008).

6. Had difficulty obtaining any administrative document (q40)

This indicator measures the share of firms that had difficulty obtaining any of the supporting documents required for starting a business (such as a certificate of fire safety or an advertisement license). Requirements vary by township and sector, but businesses are often required to obtain between 5 to 12 supporting documents to apply for operating licenses and registration certificates. Sometimes, these can be quite complicated to obtain, such as when one needs to collect signatures from neighbors to open a pub or restaurant. The more difficult it is to obtain the documents that are required to start a business, the more resources and time are spent, and the higher the overall costs are going to be (World Bank, 2018). Furthermore, the business may lose money on rent and other fixed costs if it cannot open in a timely manner since the business may have to wait for the completion of all the administrative documents before beginning operations.

7. DAO licensing (Business Operating License)

This indicator measures whether, for each state/region, the township DAO offices provide complete services for a given license or certificate—in this case, the Business Operating License. Specifically, the indicator measures whether the township DAO office is able to provide examples of required application materials, receive applications, and directly issue documents. The township scores are then aggregated up to the state level. The indicator is scored from 1 to 3, with 1 showing that the office receives applications; 2, that it receives applications and issues licenses; and 3, that it performs these functions with examples or guidance. This indicator

FIGURE 29
Entry Costs

measures entry costs directly: the more licensing processes the DAO office manages, the more streamlined the process of starting a business becomes, hence the lower the time and effort, and sometimes monetary costs, will be to start the business.

8. DAO required documents (Business Operating License)

This indicator measures the mean level, for each state/region, of supporting documents required by the township DAO to apply for a particular license or certificate—in this case, the Business Operating License. Supporting documents considered included application forms, support letters from other government offices, and signature forms for neighboring residents. The indicator is scored from 0 to 6, with 0 corresponding to no supporting documents required and 6 corresponding to six supporting documents required. In this case, we focus on general supporting documents that may apply to all industries. The more supporting documents are needed to start a business, the more cumbersome the process will be. Hence, entry costs will be higher.

Summary Statistics (Firm Respondent Level)

Variable Name	Count	Mean Firm*	SD	Min	Max
Firms waiting over 3 months to be legal (%)	4475	40.0%	49.0%	0%	100%
Number of total documents for firm to become fully legal	4592	4.4	3.9	1	99
Median days to get operating license (CDC)	4547	0.0	36.4	0	730
Median days to get operating license (DAO)	3830	7.0	46.9	0	730
Median days to get DICA registration certificate (DICA)	338	30.0	71.0	1	365
Median supporting documents required for DAO license	4592	4	3.9	1	99
Had difficulty with any administrative document	4874	9.3%	29.1%	0%	100%

*Note: Mean firm scores per indicator are displayed unless otherwise stated. In these other cases, the median is displayed.

Summary Statistics (State and Region Level)

Variable Name	Count	Median S/R	SD	Min	Max
Firms waiting over 3 months to be legal (%)	15	45.2%	14.2%	23.4%	69.0%
Number of total documents for firm to become fully legal	15	4.4	0.61	3.2	5.3
Median days to get operating license (CDC)	3	33.96	13.3	28.15	53.2
Median days to get operating license (DAO)	13	25.19	7.43	17.88	47.6
Median days to get DICA registration certificate (DICA)	15	45.5	38.3	6.1	170.0
Had difficulty with any administrative document (%)	15	9.1%	4.0%	2.4%	15.3%
DAO licensing efficiency (1-3 points)	15	3.0	0.2	2.5	3.0
DAO required documents (0-6 points)	15	4.7	1.2	2.6	6.0

*Note: S/R denotes State or Region

B.2. Indicator Descriptions and Data for Land Access & Tenure Security Subindex

Access to land and the stability of land tenure are fundamental to business performance since they affect the types of investments a business will undertake, its profitability, or whether a business can even begin operations at all. Insecure tenure of land leads to uncertainty, which means that businesses will be reluctant to pursue investments that may greatly improve long-

term profitability because they are unsure if they will be there to reap the future profits. Taken to the extreme, potential entrepreneurs may not even start a business if they think that the government can simply take their land away. Land-related issues are a significant problem in Myanmar. The majority of the population still lives in rural areas, where land is a major but rare asset. According to a report by the Ministry of Natural Resources and Environmental Conservation, the landless population is around 25% nationwide (and much higher in some areas). The report also cites land issues as a major concern for the government.

We measure land access and security with the eight following documents.

1. Whether the firm owns land and has a title (q49)

This indicator measures the share of firms (among all the firms that own land) that have a formal land title. An increased likelihood of firms owning land implies that land is easier to access in that area (De Soto, 2000). This may be for several reasons: there may be unused and available land for purchase, or the process of acquiring land is straightforward and less hindered by lack of information or bureaucratic inefficiencies. An entrepreneur's lack of a formal land title implies much lower tenure security than his/her possession of one. Absent a formal land title, the entrepreneur's land may more easily be expropriated by the government or be made more contestable by those wishing to claim it. Moreover, as titles are often used as collateral in banking transactions, no title constrains the ability to access capital and expand investments.

2. Length of time to get a land title in days (q51_1)

The number of days it takes to get a land title is a useful indicator of whether firms have difficulty obtaining titles or the process includes prolonged delays.

3. Whether the firm did NOT face obstacles acquiring land or expanding business premises (1=no obstacles)

This indicator asks entrepreneurs if they faced any difficulty acquiring land or expanding their business premises. A "yes" implies that land access is more difficult to procure. The rationale for this indicator is straightforward; if the entrepreneur faced any challenges in acquiring or expanding his land, this speaks to inefficient bureaucratic processes ("red tape"), a lack of information on how to acquire land or expand premises, or simply a lack of available land for purchase (Demsetz, 1974; Knight, 2012). This indicator can be explicitly linked to Part 5 of the National Land Use Policy (2016), which has explicitly detailed the land acquisition procedure.

4. Risk of expropriation (1=low or no risk) (q52)

This indicator is a binary variable that shows whether the firm perceives that it faces low risk of expropriation or not. The indicator gets at the heart of many issues concerning tenure stability. Stable tenure implies that the firm expects to own and operate the land for the foreseeable future—for example, for the length of time that the land lease stipulates. When the risk of expropriation (the risk that a firm's land is taken from it against its will or outside of the terms of its land contract) is sufficiently high, the firm is, by definition, insecure about its tenure (Feder and Feeny, 1991). The implications for business may be that a firm does not make the long-term necessary investments (e.g., in machinery) that are profitable only after a moderate amount of time since the firm's insecurity over its tenure may mean that these long-term investments may no longer be profitable.

5. The firm believes that it will receive fair compensation in case of expropriation (1=fair compensation)

This indicator measures the share of firms in each state/region that believe that they will receive fair compensation in the event of an expropriation. On occasion, it is necessary for government officials to engage in eminent domain—that is, taking land for public use, such as the expansion of roads or the creation of industrial zones. These activities are in the best interests of the economy but may injure individual entrepreneurs. In such cases, it is necessary to know

whether existing property holders are compensated fairly for their land. Uncertainty over fair compensation increases the cost of acquiring land since the entrepreneur is more uncertain about economic returns (McMullen and Shepherd, 2006). If fair compensation is not given, the entrepreneur would have spent money on start-up costs and on operating the business, only to lose his or her income stream for too little in return. In cases of high uncertainty, entrepreneurs may even resist investing fully in the property, preferring a wait-and-see approach. This lack of effort reduces business activity, and ultimately, employment and tax revenue. While not explicit, this indicator is consistent with the spirit of the National Land Use Policy Part 6 (2016), which describes dispute resolution and appeal.

6. The firm completed land procedures and has not encountered any difficulties (q58)

This indicator measures the share of firms in each state/region that have not encountered any difficulties when they have undertaken various land-related procedures. This is a useful and straightforward indicator of land access. If a firm encounters difficulties, this situation could easily imply that procedures to acquire land are cumbersome, confusing, or inefficient (Ciccone and Pappaioannou, 2007).

7. Risk of suddenly changing rental or lease contract (q55) (1=low risk)

This indicator is limited to firms in each state/region that are operating on rent and measures whether the firm's perceived risk of an unexpected change in the rental or lease contract is low or not. As with uncertainty over expropriation and compensation, the higher the perceived risk that a firm will face unexpected changes to the land contract, the more insecure its land tenure will be (Feder and Feeny, 1991). A sudden change in the terms of a land contract means that tenure is less stable; for example, the terms may be profitable prior to the sudden change but no longer profitable after it. In these cases, it may no longer make sense to continue the business. The ultimate implication of unexpected changes for business performance is that uncertainty over contract terms may discourage potential entrepreneurs from starting a business and may derail potentially profitable and scalable businesses, preventing them from taking off.

Land Access and Security

B.3. Indicator Descriptions and Data for Post-Registration Regulatory & Administrative Costs Subindex

Businesses incur regulatory and administrative costs as long as they are in operation. Renewing licenses, obtaining forms and supporting documentation, complying with regulations, undergoing inspections, and updating business practices are necessary for maintaining business standards. These obligations, while important, can often be arbitrary and impose significant burdens on businesses. If the costs of the procedures become excessive, then businesses face tremendous opportunity costs and may even choose to shut down operations. This, of course, has negative implications for economic growth and poverty reduction. Myanmar has substantial issues dealing with post-registration costs. For example, Myanmar is ranked 155 out of 190 countries in the World Bank's *paying taxes* indicator. This ranking implies that the process of dealing with administrative requirements (in this case taxes) is cumbersome, time consuming, and inefficient.

1. Less than 10% of the owner's or manager's time spent understanding and complying with labor regulations (q64) (1= less than 10%)

The amount of time spent understanding and complying with regulations directly is related to the costs of running a business and is hence a useful indicator of regulatory and administrative costs. The more time the owner or manager spends understanding and complying with regulations, the less time he has to manage other issues related with running the business—lowering operating costs, refining the product, or marketing the product, for example. This, in turn, may lead to lower profits (Amin, 2009). The costs referred to here are therefore mostly opportunity costs; understanding and complying with regulations takes away from time spent on income-generating business activities.

2. Median number of inspections for all regulatory agencies (q69)

The higher the median number of inspections by regulatory agencies, the higher the regulatory and administrative costs that the firm faces. The increased regulatory and administrative costs may happen for several reasons. The firm may simply have to spend more time understanding, and agreeing to potential visits from, the regulatory agencies, or complying with sanctions imposed on it by these agencies (Posner, 1974). Another potential issue may be the greater opportunity for bribery and petty corruption that arises with visits from regulators. The more bribery and petty corruption the firm faces, the less time it can spend on income-generating activities, and the fewer resources it will have to run the business.

3. Government officials are effective (q66_1) (1=effective)

This indicator measures the share of firms in each state/region who believe that government officials are effective. More effective officials are associated with lower regulatory and administrative costs. To the extent that perceptions of effectiveness are close to actual effectiveness, this indicator implies that effective government officials are both less likely to extract costly bribes from firm owners and more likely to deal with firms in a timely and predictable manner, lowering overall costs to the firm. Perceptions of effectiveness play a role in affecting costs since the perception that government officials are ineffective may dissuade firm owners from making investments in regulatory compliance (Alfonso et al., 2005).

4. The firm does not need to make many trips to obtain stamps and signatures from state agencies to complete procedures (q66_3) (1=does not need)

This indicator measures the share of firms that believe that they did not need to make many trips to complete procedures. The more visits to government offices that a firm makes to deal with regulatory procedures, the more time is spent away from income-generating activities such

as lowering operating costs or improving the quality of the product. The number of trips owners and managers need to make to complete procedures eats into funds and other resources for the business (World Bank, 2018). Multiple trips may also lead to greater uncertainty on the part of the firm owner over whether the regulatory issue in question can be resolved in a timely manner. This indicator is consistent with the National Land Use Policy (2016), which states that “Land transfer fees and stamp duties shall be fair, equitable and appropriate, and the procedures related to the collection and payment of revenue shall be clear, effective and transparent”.

5. The owner believes that the paperwork is simple (q66_4)

This indicator measures the share of firm in each state/region owners or managers within a state who believe that paperwork in relation to regulatory and administrative issues is simple. If paperwork is simple, regulatory and administrative costs are lower. There is less wasted time and less need to hire consultants or lawyers for assistance. Simplified paperwork can reduce costs for various reasons. One reason may be that simple paperwork reduces the time spent understanding and complying with regulations (see indicator above). Another reason may be that simple paperwork means that fewer mistakes are made by the firm and bureaucracy when completing the relevant procedures, which saves the firm time and money (World Bank, 2018). While the relevant list of required document is not described, required forms and submission process is explicitly described in DICA website and Investment Law.

6. Fees are publicly listed (q66_5) (1=publicly listed)

This indicator measures the share of firms in each state/region that believe that regulatory and compliance fees are publicly listed at the relevant state agencies. Publicly listed fees substantially reduce the uncertainty around regulatory procedures and hence reduce the time spent on compliance with these procedures. Publicly listed fees also lead to fewer mistakes on the part of both the firm and the bureaucracy, further reducing costs and wasted resources (Knight, 2012).

FIGURE 31

Post-Entry Regulation

B.4. Indicator Descriptions and Data for Informal Payments Subindex

Informal payments impose significant costs to firms. Paying bribes for procedures or licenses that firms should simply have the right to procure imposes an unnecessary, inefficient burden on businesses. Governments, too, can lose from corruption. For example, if a corrupt official bribes a firm that does not meet regulatory standards, the official then pockets funds that should go to the government and ideally be used for various programs and policies. Informal payments can also foster an environment that may dissuade potential entrepreneurs from even starting a new business; they may deem a climate of widespread corruption as too volatile and uncertain. Finally, corruption can damage public service delivery when unqualified vendors are chosen for delivery in biased public-procurement auctions. The country faces significant challenges with respect to informal payments. Myanmar is currently ranked 130 out of 180 countries on Transparency International's Corruption Perceptions Index 2017.

1. Firms disagree with the statement "Firms in my line of business usually have to pay gifts in the form of money" (q75) (1=NO need to pay)

This straightforward indicator of the presence and frequency of bribery and corruption is used in the World Bank Enterprise Surveys and in subnational business environment indices in other locations. Given the obscure nature of informal payments, it is usually very difficult to find data that speaks to these issues. A measure such as this one—which captures either the experiences of owners and managers paying a bribe or their perceptions of the prevalence of bribery and corruption in their line of work—allows us to quantify this important aspect of governance. Paying a gift in the form of money is clearly not a formal process necessary for establishing a business and diminishes the resources necessary for the firm's effective operations (Shleifer and Vishny, 1993).

2. Firms that do not have to pay bribes or with less than 10% of revenue in bribes (q76) (1=less than 10%)

This indicator measures the share of firms in each state/region that either paid minimal bribes (below 10% of revenue) or did not need to pay bribes in the course of doing business. The implications for the business are straightforward; if the firm has to pay a substantial amount of its revenue in bribes, it loses resources required for other parts of the business, such as rent or marketing. If the share of bribes to total revenue becomes exorbitantly high, then the firm may no longer make a profit and may need to cease operations (Bardhan, 1997). This measure differs from the previous measure (which captures frequency of informal payments) by quantifying the intensity and scale of corrupt activities in the state.

3. Owner or manager usually knows the amount of bribe to pay in advance (q77) (1=knows)

This indicator measures the share of firms in each state/region that know the amount that they will have to pay in bribes. While informal payments are problematic in their own right, knowing the amount to pay for a bribe is beneficial to the firm relative to the alternatives. This knowledge allows the firm to plan expenses and to make the necessary investments in the business while paying the bribe. Some analysts have suggested that knowing the bribe amount allows firms to treat it like a tax and adjust for it in long-term planning. The uncertainty of not knowing the amount to pay in bribes prevents firms from planning and hence making the long-term investments necessary to increase revenues and profits (Campos et. al., 1999; Malesky and Samphantharak, 2008).

4. Expected frequency of delivering the service or document if a firm makes extra payments (q78)

This variable measures the share of firms in each state/region that usually (often) receive the expected service or document on condition of having paid the required bribe. Again, while

paying a bribe is not ideal, once the bribe is paid, it is preferable to expect the delivery of the service or document rather than to remain uncertain of its delivery. Uncertain delivery of the service or document once the bribe is paid leads to inefficiencies in the firm's operation since the firm's managers cannot plan ahead and make the necessary investments to increase firm profits (Campos et al., 1999; Malesky and Samphantharak, 2008).

5. Firm owner or manager agrees with the statement "Paying a present in the form of money is essential to improve chances of winning the contract" (q81) (1=not necessary)

This indicator measures the share of firms in each state/region that agree with the statement that bribery is necessary to improve the chances of winning a contract. Agreement with this statement implies that firms perceive bribery as an important contributor to "getting things done." Perceptions of corruption and bribery may drive actual corruption and bribery; perceptions of the presence of bribery and corruption are good indicators of the actual level of bribery and corruption—which is the core concept we are trying to measure (Beck and Maher, 1986).

6. Corruption complaints per capita

This indicator measures the number of corruption cases filed with the Anti-Corruption Commission per firm for each state/region. The more corruption cases filed per firm, the greater the corruption and bribery in the state or region; the fewer corruption cases filed, the lower the corruption and bribery in the state. This measure assumes that the more corruption charges in an area, the more corrupt a place actually is. This assumption may not always be true: more corruption charges may imply that the local government is more vigilant in identifying and punishing corrupt politicians and bureaucrats, and may even identify a greater share of corrupt officials. Low corruption charges per capita may then identify a state where corruption is not taken seriously, and actual corruption may be rampant even if charges per person are low. Caveats aside, a measurement of corruption may correlate with inefficiencies and bureaucratic red tape, potentially lowering the overall output of businesses. This makes consumers worse off and leads to lower growth.

FIGURE 32

Informal Payments

information flow between the firm and its suppliers, consumers, laborers, and regulators. Poor information flow between these groups and the firm leads to inefficiencies from miscommunication (e.g., materials are needed from a supplier) or capacity limitations (e.g., a firm cannot adapt quickly to changing circumstances, for example, by informing the laborers that they need to work overtime) (Demurgur, 2001). This indicator is also explicitly linked to existing laws, as service providers need to meet a performance standard set by the Telecommunication Law (2013).

3. Electrical power is good (q86a_6)

This indicator depicts the share of firms in each state/region who think that the quality of electricity provision in their area is good. Electrical power is fundamental to many businesses. Without electricity, a business may not even be able to operate, resulting in lost resources and potential revenues. Even when electricity is provided, unannounced blackouts hurt firms in a similar fashion; firms lose potential revenues since they cannot adjust to blackouts that they cannot predict (Shiu and Lam, 2004).

4. Number of hours lost of telephone, fax, and Internet (q94_1)

The number of hours lost of communication and information technology is a good indicator of infrastructural quality. Poorly functioning IT proxies for the quality of service provision in the state. Hours lost may imply that the proper infrastructure for the sufficient provision of these services (e.g., telephone lines that are not easily destroyed) is not yet in place. Losing hours of functioning telephone, fax, and Internet directly affects a firm since it can lose potential revenues from its inability to communicate its plans and decisions to suppliers, consumers, employees, and regulators (Demurgur, 2001).

5. Hours of lost power in the last month (q90_1)

Similar to the previous indicator, hours of lost power in the last month is a helpful proxy for the underlying infrastructure and has direct implications for firms. Losing power means that firms cannot operate, and hence they lose revenues. This holds true even if power is usually available but a loss of power is unpredictable; for example, if employees work on a day when the power fails, the firm—without any revenue generation—still needs to pay for the cost of labor (Demurgur, 2001).

6. Number of days road blocked in a landslide (q87_1)

The number of days a road is blocked in a landslide serves as a measure of both existing infrastructural quality and the state/region government's capacity to deal with infrastructure-related issues. Apart from proxying for the infrastructure needed to prevent landslides, this measure also indicates how effective the state is when it comes to dealing with infrastructural problems: more days means that the state is less effective, less days means it is more effective. For example, if the state can remove debris from a landslide quickly, this achievement suggests that the state may have the resources and know-how to deal with various sorts of unforeseen disasters (e.g., typhoons) that may affect the state infrastructure (Calderon and Serven, 2004).

7. Internet is good (q86a_9)

The share of firms responding that Internet quality is good is a sound indicator of infrastructural quality. A poorly functioning Internet proxies for the quality of service provision in the state or for a potentially uncompetitive market for Internet provision (monopoly or duopoly). Poor Internet quality affects firms directly since the Internet is a means by which firms gather information and communicate with suppliers and customers. Poor Internet therefore implies inefficiencies and the potential loss of revenue and profits (Calderon and Serven, 2004).

8. Percent of the population with TV

9. Percent of the population with electricity

10. Percent of the population with a telephone

These three indicators measure the share of the population with a TV, electricity, and a telephone, respectively, for each of the 15 states. The indicators (with the possible exception of the TV share indicator) measure physical investments that are necessary to the functioning of a business. A firm cannot run without electricity, and most firms need phones to communicate with suppliers or clients. Moreover, all these indicators require a functioning infrastructure to operate; thus, they also measure the quality of the physical infrastructure—telephone and electrical lines, for example—that the state provides.

FIGURE 33
Infrastructure

Summary Statistics (Firm Respondent Level)

Variable Name	Count	Mean Firm*	SD	Min	Max
Roads are good or very good	4859	49.0%	50.0%	0%	100%
Telephones are good or very good	4854	65.9%	47.4%	0%	100%
Electrical power is good or very good	4806	49.7%	50.0%	0%	100%
Median hours lost of telephone, fax, and internet	2825	20	1661	0	43200
Median hours of lost power in last month	4489	20	59	0	700
Median number of days road blocked in a landslide	1791	7	44	1	365
Internet is good or very good	4642	54.2%	49.8%	0%	100%

*Note: Mean firm scores per indicator are displayed unless otherwise stated. In these other cases, the median is displayed.

Summary Statistics (State and Region Level)

Variable Name	Count	Median S/R	SD	Min	Max
Roads are good or very good	15	43.5%	21.0%	13.6%	89.2%
Telephones are good or very good	15	71.8%	9.9%	45.0%	81.5%
Electrical power is good or very good	15	52.4%	14.2%	33.7%	76.5%
Median hours lost of telephone, fax, and internet	15	198	166	58	697
Median hours of lost power in last month	15	26	17	15	67
Median number of days road blocked in a landslide	15	16.5	16	5	67
Internet is good or very good	15	52.3%	8.1%	37.7%	65.7%
Population share with electricity	15	42.9%	10.9%	28.2%	65.8%
Population share with TV	15	47.4%	20%	5.8%	83.7%
Population share with a telephone	15	55.6%	12.1%	32.3%	75.3%

*Note: S/R denotes State or Region

B.6. Indicator Descriptions and Data for Transparency Subindex

Government transparency is the clarity and predictability of government activities and policies such that firms can make informed decisions. Simply stated, government transparency allows firms to be more efficient and hence more profitable. Well-informed firms can make better decisions about the direction of their business. Access to government documents and the predictability of changes to government laws and regulations help to increase government transparency. The Myanmar Transparency Report 2018 highlights some of the outstanding transparency issues facing the country. According to the report, transparency helps mitigate investment risk and aids in the recruitment and retention of qualified staff.

1. Access to planning and legal documents (q132_1 to q132_10)

This indicator is the sum of ten variables, each variable measuring the share of firms in each state/region that believe it is easy to access some kind of local document of information. The ten variables include state/region budgets, township budgets, union laws and regulations, and public investment plans. Access to these planning and legal documents is a direct measure of the state's transparency—that is, the willingness and ability to disclose and disseminate public information. The more a state is willing to grant access to documents, the more transparent it is. A government's transparency may benefit firms because access to state documents means that firms are better able to plan their long-term investments, reducing their downstream risk (Broz, 2002; Gelos and Wei, 2005; Knight, 2012; Stasavage, 2003). Transparency of documentation is explicitly required under a number of legal documents. For example, the Union Budget Law requires that both federal and state/region governments publish budgets annually in a way that is easily available to citizens.

2. Predictability of the changes of laws and regulations at the union level (q137_1 and q137_2)

This indicator is the sum of two variables—the share of firms in each state/region that believe that changes in laws and regulations at the union level are at least usually predictable, and the share of firms in each state/region that believe that implementation of regulations at the local level are at least usually predictable. Predictability of the changes of laws and regulations is a useful proxy for transparency. In more transparent states, not only are state documents readily

provided but future government plans are clear to its constituents. Such clarity is beneficial for firms because they can plan their operations to work within the expected new laws and regulations. If changes to laws and regulations are unpredictable, firms may unexpectedly find themselves in violation of these laws and will have to spend resources and time adjusting quickly. This process of readjustment is usually more costly than timely planning in light of expected changes (Gelos and Wei, 2005; Hollyer et al., 2011; Malesky et al., 2015).

3. Percent of DAO documents with examples provided (Business Operating License); Percent of DALMS documents with examples provided (Record of Immovable Assets)

These two indicators measure, for each state/region, the extent of information available publicly or upon request for a particular DAO or DALMS service—in this case, providing businesses with an operating licenses and Record of Immovable Assets, respectively. The state or region score is the average score for each of the surveyed townships within that state or region. These indicators measure the percentage of relevant documents (e.g., application forms and support letters from other government offices) for which examples are provided at the DAO or DALMS office. The indicator is scored from 0 to 1, with 1 corresponding to extensive information provided and 0 corresponding to no information provided. The extent to which examples are provided speaks directly to the transparency of these government offices. The more examples provided, the more information prospective entrepreneurs and existing firms have in order to correctly and efficiently go through the process of starting a business or of complying with existing regulations.

4. Level of information posted on one-stop-shops (0-5)

This indicator measures, for each state/region, the degree of information publicly posted at township one-stop-shop (OSS) offices. The state or region score is the average score for each of the surveyed townships within that state or region. The information assessed included

FIGURE 34

Transparency

publicly posted signboards, example licenses, schedules of fees, sample-required letters, and hours of operation for 10 desks located within the OSS. The indicator is scored from 0 to 5, with 5 corresponding to extensive information provided and 0 corresponding to no information provided. Similar to the indicator above, the more examples provided, the more information prospective entrepreneurs and existing firms have in order to correctly and efficiently go through the process of starting a business or of complying with existing regulation.

5. Percent of information posted at GAD, DAO, and DALMS offices

These three indicators measure the extent of information publicly posted at township GAD, DAO, and DALMS offices. The state score is the average of the scores for each surveyed township within a given state. A higher score implies that the township offices were more informative on average. The information assessed included example forms and certificates as well as required procedures for activities such as change of land title or use. The indicator is scored from 0 to 1, with 1 corresponding to extensive information provided and 0 corresponding to no information provided. These indicators directly assess transparency because they measure the presence and extent of readily available information for anyone who wants to start a business.

Summary Statistics (Firm Respondent Level)

Variable Name	Count	Mean Firm *	SD	Min	Max
Access to planning and legal documents: state/region budget	1320	6.3%	24.3%	0%	100%
Access to planning and legal documents: township budget	1507	5.8%	23.3%	0%	100%
Access to planning and legal documents: Union laws and regulations	2076	11.4%	31.8%	0%	100%
Access to planning and legal documents: implementing documents of Union ministry	1332	4.8%	21.4%	0%	100%
Access to planning and legal documents: legal documents at state/region level	1471	4.0%	19.6%	0%	100%
Access to planning and legal documents: new infrastructure plans	1802	4.3%	20.2%	0%	100%
Access to planning and legal documents: public investment plans	1674	3.6%	18.6%	0%	100%
Access to planning and legal documents: land use allocation plans and maps	2166	9.9%	29.8%	0%	100%
Access to planning and legal documents: planning for the development of local industries and sectors	1696	4.7%	21.1%	0%	100%
Access to planning and legal documents: forms for fulfilling regulatory procedures	3119	26.9%	44.4%	0%	100%
Low frequency of changes in laws and regulations at the Union level (%)	4874	71.1%	45.3%	0%	100%
Low frequency of changes in the regulations at the local level	4874	66.1%	47.3%	0%	100%

*Note: Mean firm scores per indicator are displayed unless otherwise stated. In these other cases, the median is displayed.

This indicator measures the share of firms in each state/region in agreement (or disagreement) with the claim that the favoritism of local authorities toward well-connected businesses affects the firm's business operations. This is a clear indicator of bias toward big business and can lead to less competition in the industry. For example, if local authorities favor a particular rice mill, they may inadvertently worsen the business environment for other operations through difficulties in administration as well as access to land and capital. If favoritism is extremely severe, it may drive healthy businesses out of the market. This can result in limited competition and consequently higher prices and lower quality, ultimately hurting consumers and businesses—in this example, the candy producers who rely on the rice mill for intermediate products (Stigler, 1957; Hellman et al., 1999).

2. Privileges and favoritism to businesses with strong connections for land access (q179_1) (1=no favoritism)
3. Privileges and favoritism to businesses with strong connections in access to loans (q179_2) (1=no favoritism)
4. Privileges and favoritism to businesses with strong connections in granting mineral exploitation license (q179_3) (1=no favoritism)

Favoritism toward well-connected firms in terms of specialized inputs—land access and access to loans—may have substantial negative effects on competition. The favored firms for land or loan access are often selected not on merit (i.e., whether they provide the product consumers most want at a low price and of the preferred quality) but because the firm owners are connected to local politicians (Claessens et al., 2008). Since merit is not the ultimate selection criteria, the product of politically connected, favored firms may be inferior, hurting consumers. There are also indirect effects on the market structure of industries where certain firms are favored. A well-connected firm may end up controlling the market, leading to monopolies and lower quality, more expensive goods. Restraints in business competition are specifically described and outlawed by the Competition Law (2015).

FIGURE 35

Favoritism in Policy

5. Privileges and favoritism lead to simpler and less time-consuming administrative processes for select firms (q179_4)

Privileges and favoritism leading to less time-consuming administrative processes is not only a direct measure of bias but also hurts firms that are not privileged. Firms that are not connected, and hence must face more cumbersome and time-consuming administrative procedures, are at a disadvantage. Their time and effort, and potentially their resources, are disproportionately spent on administrative processes, leading potentially to lower profits and an uneven playing field, where favored firms can spend more time on income-generating activities (Fisman, 2001; Li et al., 2008).

6. Privileges and favoritism lead to more easily obtaining state agencies' contracts (q179_5)

Privileges and favoritism in procurement is a direct measure of competition policy bias and directly affects the market structure of an industry (Hellman, 1999; Stigler, 1957). If more favored firms more easily obtain state contracts, then these contracts may be awarded to less efficient and less innovative firms at the expense of non-connected yet more efficient and profitable firms. This affects the quality of industry and ultimately affects consumer welfare.

7. Privileges and favoritism to businesses lead to easier access of information (q179_6)

If more connected and privileged firms get access to information, this may mean that firms that benefit from this information are not necessarily the most efficient and profitable firms. This may result in lower quality output in the market and the perpetuation of inefficient rent-seeking firms at the expense of more innovative, scalable ones (Fisman, 2001; Xu et al., 2013).

8. & 9. Banks and Micro-Financial Institutions (MFIs) per 10,000 people

These two indicators measure the number of banks and MFIs per 10,000 people, in each state/region, respectively. More banks and MFIs per capita imply less competition policy bias. The logic behind these indicators is that the more banks and MFIs there are, the more equitable the access to capital, and hence the more open economic competition will be. A caveat is that these indicators may not precisely measure the variation in how these banks and MFIs work. For example, MFIs in some states may have more stringent loan terms than those of other states, which implies tougher access to capital in the former case. Nevertheless, these measures provide relatively direct evidence on access to capital.

Summary Statistics (Firm Respondent Level)

Variable Name	Count	Mean Firm*	SD	Min	Max
No favoritism of local authorities toward businesses with strong connections	4874	75.0%	43.3%	0%	100%
Favoritism in land access	1220	64.0%	48.0%	0%	100%
Favoritism in access to loans	1220	44.6%	49.7%	0%	100%
Favoritism in granting mineral exploitation license	1220	6.3%	24.3%	0%	100%
Favoritism in administrative procedures	1220	25.2%	43.4%	0%	100%
Favoritism in state contracting	1220	19.8%	39.9%	0%	100%
Favoritism in access to information	1220	17.0%	37.5%	0%	100%

*Note: Mean firm scores per indicator are displayed unless otherwise stated. In these other cases, the median is displayed.

Summary Statistics (State and Region Level)

Variable Name	Count	Median S/R	SD	Min	Max
No favoritism of local authorities toward businesses with strong connections	15	75.1%	12.4%	47.4%	93.9%
Favoritism in land access	15	60.1%	13.6%	27.8%	83.9%
Favoritism in access to loans	15	36.7%	14.9%	10.4%	61.9%
Favoritism in granting mineral exploitation license	15	4.1%	4.6%	0.0%	13.0%
Favoritism in administrative procedures	15	23.9%	18.3%	5.0%	72.2%
Favoritism in state contracting	15	15.2%	16.3%	0.0%	57.5%
Favoritism in access to information	15	19.0%	11.5%	1.6%	36.4%

Micro-finance institutions per 10,000 citizens	15	0.26	0.53	0.05	1.74

*Note: S/R denotes State or Region

B.8. Indicator Descriptions and Data for Environmental Compliance Subindex

Complying with environmental regulations is essential for both businesses and citizens. Poor environmental quality affects the health of firm workers and citizens, leading to lower productivity at work. Pollution may also affect the products of firms, such as agricultural commodities or services like tourism. Some businesses are likely to enact environmentally damaging policies if left to their own devices. Local governments must therefore ensure that firms comply with the regulatory conditions established in the law. Myanmar faces significant challenges relating to environmental compliance. An Asian Development Bank Report notes that “the lack of a comprehensive and coordinated environmental framework, enabling institutional and legal structures, expertise, and greater capacity for natural resource management and funding” are among the country’s outstanding challenges (Raitzer et al., 2015).

1. High level of overall environmental quality (q150)

This indicator measures the share of firms in each state/region that believe that the state has high overall environmental quality. High environmental quality matters both from the perspective of society in a broad sense and has implications for firm profits (Dasgupta, 2000; Newlands, 2003). Poor environmental quality negatively affects citizens’ quality of life (pollution is unpleasant) and may directly affect health (e.g., disease transmission from insects like mosquitos that thrive in polluted environments). Firms may contribute to pollution if they are not regulated by the government. Pollution also affects firms directly. For example, polluted environments may make laborers sick or less productive, and polluted environments are less palatable to potential investors and customers. Environmental quality is explicitly addressed in Myanmar’s EIA Procedures (2015) and Environmental conversation law (2012).

2. Severity of pollution is at an acceptable level (q151)

This indicator measures the share of firms in each state/region that believe that the severity of pollution in a state is at an acceptable level. This indicator is another way of getting at environmental quality and is helpful in identifying the same effects as the previous indicator (Jaggi and Freedman, 1992).

B.9. Indicator Descriptions and Data for Labor Recruitment Subindex

Labor policies, such as labor training and labor recruitment, affect the costs of doing business and the quality of the firm's final product. Labor policies ultimately affect the quality of a firm's human capital: the higher the quality of workers, the more productive a firm will be. Mismatches in the labor market affect both worker and firm; workers end up in unsuitable jobs, preventing them from maximizing their wages, and firms are less productive and have to spend more on training workers. Reasonable and efficient labor policies are therefore an important component of a healthy business environment. Myanmar has made notable changes to its labor regulations. According to the World Bank Doing Business Report 2019, Myanmar has introduced a minimum wage and changed the regulation of severance pay. With these substantial changes, it is thus important to assess how local governments perform in the realm of labor regulation.

1. Percentage of total business costs spent on labor training

This indicator measures the average costs that firms in each state/region spend on labor training. The more money a firm spends training labor, the less money it has for productive use and hence for making profits. The costs spent on labor training also imply inefficiencies in the labor market. For example, employers are ill-informed about the skill level of labor, or state regulations are inefficient or excessively burdensome, leading to poor matches between laborer and firm (Mincer, 1962). Apart from the direct implications for firm performance, this measure also speaks to the overall educational environment created by the state; in a low-quality educational environment, the state is not training a productive labor force through vocational or general education. A related law is the Employment and Skills Development Law (2013), in which Chapter 5 states that "Employers shall conduct occupational training to enhance the skills of workers who are to be employed as well as workers who are presently employed in accordance with the requirements of the enterprise and the policy of the Skills Development Agency".

2. Ease of labor recruitment (q96_1 to q96_5)

This indicator is a sum of various measures. It shows the share of firms in each state/region that believe that labor recruitment for various positions within the firm for different types of employees (rank-and-file workers, technicians, accountants, supervisors, and managers) is easy. This measure has direct implications for firms and also speaks to the underlying labor policies that the state has put in place. The direct implications are clear: more difficult labor recruitment processes increase costs to the firm and decrease profits, and more mismatches in the labor market between worker and firm lead to greater inefficiencies in firm functioning and to lower profits (Blanceflower et al., 1996; Ponte, 2000). Difficulty of labor recruitment may imply that labor policies are leading to market inefficiencies. For example, excessively stringent rules on hiring (quotas, age limits, strict terms on labor contracts) reduce the flexibility of firms to hire the best workers and hence further affect the firm's performance.

3. Percentage of the population that has completed primary education

4. Percentage of the population that has completed middle school education

These two indicators measure the share of the population in each state/region that has completed a primary and middle school education, respectively. These indicators measure the quality of human capital in the state, to the extent that education proxies for human capital. The higher the percentage of both indicators, the better the state does in the labor policies subindex. This indicator takes education policies as a type of labor policy and measures the degree to which education policy leads to higher-quality human capital.

B.10. Indicator Descriptions and Data for Law & Order Subindex

Law and order refers to the bundle of legal, political, and institutional arrangements that allow firms to undertake market transactions and economic activity. Law and order spans protection from physical harm or theft to legal protection and enforcement contracts between business partners. Greater law and order therefore leads to higher expected returns when businesses engage in formal contracts, invest in physical infrastructure and land, and engage in long-term business planning, among many other potential benefits. Myanmar faces substantial issues regarding law and order. The country ranks 188 out of 190 countries on the World Bank Doing Business 2019 enforcing contracts indicator. Poor performance in *enforcing contracts* speaks to the legal impediments that the country faces.

1. Belief that if a state official breaks the law, the firm can appeal to a higher authority for resolution (q148)

This indicator measures the share of firms in each state/region that believe that if a state official breaks the law, the firm can usually appeal to a higher authority for resolution. This measure has implications both for firms and for the state's capacity to uphold law and order. If a firm believes that it can seek resolution from the state when violations are committed by state-government members, state officials may be deterred from potential wrongdoing because they fear losing their jobs or being reprimanded by their superiors. This belief may imply that the state is responsive to violations of law and order, allowing firms to operate in a safe, predictable environment. A peaceful and law-abiding environment benefits the firm through many channels (Demirguc-Kunt and Maksimovic, 1998). For example, states that have low levels of law and order are less attractive to investors (Busse and Hefeker, 2007). Law and order also prevents potentially lawbreaking firms from gaining an unfair advantage in the market. A legal mechanism to carry out punishment for law-breaking is stated in the Anti-Corruption Law (2013), which states that "If any Political Post Holder is convicted for committing bribery, he/she shall be punished with imprisonment for a term of not more than 15 years and with a fine".

2. Belief that if a state official breaks the law, the government will discipline the offending staff (q149)

This indicator measures the share of firms in each state/region that believe that if a state/region official breaks the law, the offending staff member is usually disciplined. This measure works similarly to the measure above, with implications for both the firm's performance and the state's capacity to uphold law and order (Busse and Hefeker, 2007; Demirguc-Kunt and Maksimovic, 1998).

3. Legal systems uphold property rights and contracts (q159)

This indicator measures the share of firms in each state/region that believe that the state/region legal system usually upholds property rights and contracts. The upholding of property rights and contracts has large implications for firm performance, investment, and ultimately economic development. Without secure property rights and contracting, firms will be unsure whether the investments they make will bear fruit (De Soto, 2000; Demsetz, 1974). If the state expropriates their property or a supplier cheats them out of a contract, then the investment will cost them without any return. Firms that are uncertain may desist from making these investments in the first place. Without firm investment the overall productivity of the industry will suffer, perhaps leading to fewer jobs and lower growth.

4. Firms assessment of the security situation is good (q167)

This indicator measures the share of firms in each state/region that believe that the security situation in the state/region is good. If the state's security situation is good, firms will feel that their property and assets are more secure (e.g., less likely to be vandalized or stolen), which

allows firms to spend less on security and to make investments, knowing that their physical investments will be safe, at least from physical threat. Increased security ultimately leads to improved firm performance (Gaviria, 2002; Schnatterly, 2003).

5. The firm experienced a theft or break in during past year (q168)

This indicator measures the share of firms in each state/region that experienced a theft or break-in in the past year. This is a direct measure of law and order since physical violence and violence to property are basic and observable types of violence. The state's inability to deter such crimes implies that it lacks a basic infrastructure for law and order, and that it may also be weak in other less visible dimensions—for example, corruption (Gaviria, 2002; Schnatterly, 2003).

6. Crime per capita

This indicator measures the number of crimes—such as robbery, murder, and kidnapping—committed per person for each state/region. Higher crime per capita leads to a lower score on law and order, while lower crime per capita implies greater law and order. This indicator is a direct measure of the security situation in the state. Crime deters investment by compromising the physical safety of a firm's employees and by reducing the entrepreneur's expected returns on investment. The expected returns on investment are reduced because crimes diminish an area's attractiveness for business, decreasing consumer demand as well as increasing the odds that the investment may be stolen or destroyed—which makes investments less worthwhile in the first place.

Summary Statistics (Firm Respondent Level)

Variable Name	Count	Mean Firm*	SD	Min	Max
If official violates law, he will be punished (share agree)	4874	48.7%	50.0%	0%	100%
If staff violate law, they will be disciplined (share agree)	3688	44.9%	49.7%	0%	100%
Legal system will uphold property rights and contracts	4874	70.8%	45.5%	0%	100%
State courts judge economic cases by law	1867	84.3%	36.3%	0%	100%
State court resolves economic cases quickly	1867	61.7%	48.6%	0%	100%
Court judgements are enforced quickly	1867	70.3%	45.6%	0%	100%
Legal aid supports businesses	1867	75.5%	43.0%	0%	100%
Judgement by the court is fair	1867	61.6%	48.6%	0%	100%
Security situation is good	4874	37.5%	48.4%	0%	100%
Victim of a crime last year	4874	11.2%	31.5%	0%	100%

*Note: Mean firm scores per indicator are displayed unless otherwise stated. In these other cases, the median is displayed.

Summary Statistics (State and Region Level)

Variable Name	Count	Median S/R	SD	Min	Max
If official violates law, he will be punished (share agree)	15	48.3%	12.4%	18.8%	66.0%
If staff violate law, they will be disciplined (share agree)	15	41.5%	11.8%	23.0%	60.0%
Legal system will uphold property rights and contracts	15	74.7%	12.0%	53.3%	91.8%
State courts judge economic cases by law	15	84.3%	7.1%	71.1%	93.0%
State court resolves economic cases quickly	15	62.6%	16.5%	16.2%	85.1%
Court judgements are enforced quickly	15	71.8%	14.1%	27.6%	91.0%
Legal aid supports businesses	15	79.3%	15.3%	28.9%	92.6%
Judgement by the court is fair	15	61.8%	15.0%	26.3%	87.0%
Security situation is good	15	37.5%	19.1%	1.3%	80.8%
Victim of a crime last year	15	12.9%	3.3%	5.6%	16.3%
Crimes per capita	15	0.60	1.86	0	6.12

APPENDIX C

Analysis of Strength of Preferences for Clean Environment

One concern with directly surveying businesses about preferences is that they may not report their true environmental preferences or may inaccurately estimate the trade-off between enhanced environmental regulation and business performance. We address this concern by using a conjoint, survey-experiment framework, which allows us to estimate the influence of each factor—both economic and environmental—on the formation of firms’ policy preferences in the absence of social desirability and unobserved heterogeneity across responses. Conjoint analysis allows researchers to design multidimensional treatments in survey designs and to evaluate which dimension has the most weight in determining the outcome (Hainmueller et al., 2014). In our case, this design is especially useful in determining the factors that influence environmental preferences because the candidates up for selection—the firms—vary on a number of dimensions, including size, sector, ownership type, and country of origin.

The conjoint analysis further helps our analysis in two ways. First, because it randomizes the investor’s features, it can ensure that environmental consciousness is orthogonal to other features, such as sector or country of origin, which may also be attractive to respondents. Second, a conjoint analysis provides shielding for respondents, such that it should reduce the role of social desirability in biasing respondents’ answers to questions about the environment. Similar to the list experiments used to measure the frequency of informal payments, respondents can select an investor without having to reveal the motivation behind their choice. Thus, the design limits social desirability because respondents can claim multiple alternative justifications for any choice.

The design of our survey experiment is displayed in Table 7. Using electronic tablets to administer the survey question, we vary seven features of a prospective investment into the respondent’s locality. These include whether the firm 1) comes from Myanmar, a developed country, or another developing country, 2) is owned by a private investor or is state-owned, 3) is involved in food processing, electronics, or mining, 4) will bring a small (100), medium (1,000), or large (10,000) number of jobs to the respondent’s township, 5) has ever been cited for violating environmental regulations, 6) received a targeted subsidy from the local government in the form of a tax incentive, and 7) is voluntarily following environmental standards in its operations. These features are randomized, such that different combinations of these variables show up on the tablet for each respondent, much like a slot machine in a casino. Each respondent is then asked to evaluate the investor profiles based on the combination of attributes. After being presented with the profiles of two investors, respondents are asked: “Which of these businesses would you most like to see granted approval to commence their investment project in your township?”

We find that environmental concerns play a tremendous role in the selection of prospective investors into the locality. Figure 39 presents our estimates of the influence of investor characteristics on respondents’ willingness to grant investor licenses to applying businesses. The graph plots the estimated effect of a given value for each investor characteristic on the probability of granting an investor license. The interpretation of each estimate is relative to the reference category for that dimension.

Factors concerning the business’ environmental records and operation standards are major determinants of individual investor preferences among respondents in Myanmar. First, we interpret respondents’ sensitivity to the specific sector of the future investment as individuals’ preference for less pollution-intensive investments. Investment from the mining industry, which may be associated with a considerable burden on the natural environment, decreases respondents’ desire to grant an investor license by as much as 25% relative to food processing. Electronic manufacturing decreases support relative to food processing by 7%.

Second, when asked what type of investor they would rather see being granted an investment license, respondents' preferences are strongly driven by the investor's environmental record. In particular, a history of violating environmental regulations significantly decreases the respondent's willingness to grant the investor a license. For example, violations against environmental regulations that caused damage to 100 households decreases people's willingness to support the business' license application by 26%. Environmental offences that created greater damage further reduces the business' chances of being granted an investor license; in particular, compared to a business that has not committed any environmental offences, a business that has been previously cited for environmental violation that caused damage to 1,000 households has a notable 34% lower probability of being selected.

TABLE 7
Conjoint Matrix of Investor Profiles

Attribute	Random option 1	Random option 2	Random option 3
National origin	Myanmar	Developed foreign investor	Developing foreign investor
Ownership	Private	State owned	---
Sector	Food processing	Electronics	Mining
Employment	100	1,000	10,000
Tax reduction offer	No offer	5%	10%
Past environmental violation	Never been cited	Cited for damage to 100 households	Cited for damage to 1,000 households
Green certification	Possesses a "green certificate" indicating it is now employing operations that minimize environmental damage	Does not possess a "green certificate" indicating it has not employed operations that minimize environmental damage	Is applying for a "green certificate" indicating it will employ operations that minimize environmental damage

At the same time, if the prospective investor is making an effort to apply environmentally friendly standards in its operations, then this effort significantly increases individuals' willingness to grant the firm an investment license. For example, the intention to apply for a green certificate, which implies that the prospective firm will employ operation procedures to reduce environmental pressure, increases respondents' support for the firm's application for an investor license by 10% over no application. An ongoing commitment to apply procedures that minimize environmental damage in its operations also significantly increases people's willingness to grant the business an investor license. Compared to a business that does not follow any such certified procedures in its production, a business that possesses a green certificate enjoys a 15% higher probability of being preferred by respondents. Consequently, a business with a bad environmental history may be able to make up for its past bad environmental behavior by applying certified environmentally friendly operation procedures or by showing a commitment to do so in the future. Nevertheless, the large size of the estimated effect of the investor's environmental record indicates that bad environmental behavior can only be partly compensated for.

FIGURE 39

Environmental Preferences in Investment Allocation

Endnotes

1. Generally speaking, in Myanmar “registration” is used to refer to company registration under the 2017 Companies Law. However, this registration process is not compulsory for all Myanmar companies, and most SMEs do not go through this process. Instead, for most businesses interviewed for this study, the beginning of operations requires the acquisition of an operating license from the township DAO. As such, in this study, the term “post-registration” is used to refer to the period after which a business is formally permitted to begin operations.
2. Some agricultural businesses do enter the survey indirectly due to miscoding of their industrial sectors in the sample frame or to changes in their businesses since they responded to the MOLIP survey.
3. For a more detailed explanation of Myanmar’s subnational governance framework, see Batcheler (2018).
4. The Union of Myanmar comprises 330 townships, varying in population from 1,732 to 687,867, according to data from the 2014 Myanmar census. For a more detailed description of Myanmar’s administrative structure, see Batcheler (2018).
5. Admittedly, Vietnamese companies in the PCI survey are larger and more formalized than their counterparts in Myanmar, which may influence the entry costs. Every Vietnamese business in the PCI survey has a formal registration certificate, whereas most of the businesses in the MBEI survey possess only a single-year operating license. Further, 73% of businesses in the MBEI have ten or fewer employees and 52% have five or fewer employees. Indeed, the median MBEI business has four employees compared to eight in the Vietnamese PCI. Finally, as we show in Appendix A, Myanmar businesses appear to be highly concentrated in a few sectors, particularly food processing, whereas the PCI sample is far more diverse, including a wide range of services and sectors.
6. Indeed, road quality led to the cancellation of our research interviews in two townships, so the research team is very familiar with the problem.
7. The documents required to acquire an operating license or secure other documentation may differ depending on the business type. For consistency, a standard set of documents was considered in all townships: for a DAO or CDC operating license, the set of documents included a standard application form, signatures from neighboring households, and letters of support from the Fire Department, Ward Administrator, Township Administrator, and Health Department; for a support letter from the GAD, documents included a formal request letter and supporting documents from at least one ministry; for a land lease certificate from DALMS, documents included a formal request letter, supporting documents from at least one ministry, and completion of Forms 103, 105, and 106.
8. Business confidence likely comes from the fact that they have not had to use courts to adjudicate disputes. Because this overconfidence is observed in every state and region, it biases scores on this index upward everywhere. There is little indication that the upward bias is greater in any particular state or region. As a result, the perception bias has little influence on the rankings or weighting of the subindices, which are driven by variation across states and regions.
9. Using score alone is not helpful for choosing strengths and weaknesses because the scores for subindices have different distributions. A score of 5 on transparency would be quite good, leading to a high ranking, but a 5 on land would lead to one of the lowest ranks in the country. Consequently, ranking is more helpful for this benchmarking exercise.
10. We take the natural log of nighttime luminosity data to address non-normality in the distribution.
11. Note that while we did not include agricultural firms in our sample frame, some were captured indirectly because their industrial codes were listed incorrectly in the sample frame or business operations had changed.
12. A previous iteration of this dataset was used for the 2017 UNDP Myanmar Business Survey.
13. Survey weights are included in the dataset. Please let the researchers know if you want to analyze them in more detail or use them in your own work. The researchers can provide advice on how to construct and analyze them.
14. Assuming 95% confidence intervals and a 3% margin of error around estimates.
15. For example, several townships in Shan State were dropped from the sample due to security concerns for the field team, while other townships there and in Yangon Region were added to account for nonresponse or smaller-than-expected business populations.
16. It also makes it easier to catch cheating by looking at deviations in state/region and township scores across respondents.
17. This is the same methodology used by authors of the Growth Competitiveness Index and Vietnam Provincial Competitiveness Index.
